

Signal Bus SYM

Article Overview

A signal bus is a structured communication channel that allows multiple signals to be transmitted between components in automotive or simulation systems, enabling modular, scalable, and decoupled system design.

Overview

A signal bus acts as a centralized conduit for signals, allowing different subsystems or components to exchange information without direct dependencies. In automotive systems, this is analogous to a CAN bus or AUTOSAR COM layer, where each ECU (Electronic Control Unit) can send and receive signals independently of other ECUs, ensuring that initialization order or hardware differences do not affect communication. In simulation environments like Simulink or Simcenter Amesim, signal buses serve as containers for multiple signals, simplifying model complexity and maintaining clarity.

Structure and Implementation

- **Simulink Bus Objects:** In MATLAB/Simulink, a Simulink.Bus object defines the architecture of a bus, including element names, hierarchy, order, and data types. Each bus contains Simulink.BusElement objects specifying individual signal properties. This is similar to a C struct, defining the layout without creating the actual bus.
- **Expandable Connectors:** In Modelica-based systems, a signal bus can be modeled using expandable connectors, allowing signals to be added dynamically. Signals are named systematically, often starting with the subsystem name followed by "Bus" a...
