

# What level of power supply does a secondary distribution box have

## Overview

The most common voltage levels used in distribution networks are 33kV, 22kV, and 11kV for primary distribution and 415V and 230V for secondary distribution. Let's make an example for clarity: A newly constructed residential area introduces a 10kV power line to a substation. From the transformer's low-voltage side (0.4kV), power is distributed to a main distribution panel. The outgoing line from the low-voltage end of the transformer is 0.4kV to the distribution cabinet (primary distribution cabinet), then the outgoing line is led to the distribution box (secondary distribution box) in each building, and finally the outgoing line is led to the distribution cabinet. After stepping down, secondary voltages like 415V (three-phase) and 230V (single-phase) are used to supply power directly to homes and small businesses. Spot Networks are used for customers with the highest reliability requirements.
